ABSTRAK
Produksi daging sapi di Bali didominasi oleh peternakan rakyat, sama halnya dengan
keadaan pertanian pada umumnya di Indonesia. Berbagai kebijakan telah dilaksanakan untuk
mengembangkan sapi Bali. Pengetahuan mengenai distribusi manfaat/keuntungan yang
diterima dari pengembangan sapi sapi Bali akan membantu dalam proses pengambilan
keputusan. Tulisan ini menganalisis manfaat dari pengembangan sapi Bali dalam sistem
produksi bertingkat dengan menggunakan model “equilibrium displacement’ (EDM).
Manfaat/keuntungan diukur dari perubahan surplus ekonomi pada peternak, rumah potong
hewan dan pengecer.

Kata Kunci: Produksi Daging Sapi, Kebijakan Pemerintah, EDM, Surplus Ekonomi.

INTRODUCTION
Changes in food consumption patterns in Indonesia resulting from increases in
income, urbanisation and population growth have led to changes in Indonesian agricultural
production and trade. There have been some attempts to improve productive capacity, but in
many cases such as beef cattle, production has not been able to keep pace with the increase in
consumption, encouraging imports of live cattle and beef products. Smallholder farms using
basic technology with relatively low levels of productivity dominate beef production, just like
the majority of the Indonesian agriculture.

The island of Bali is one of the cattle producing areas for Indonesia. An indigenous
Indonesian cattle breed, Bali cattle (Bos sondaicus), is kept pure on the island of Bali despite
the wide spread of this breed throughout the country. This policy was enacted to maintain and
improve domestic animal genetic resources. Bali cattle are known for their desirable traits.
These include good adaptation to arid conditions, high fertility and good meat production.
They are highly efficient in producing lean with a low fat percentage beef (Masudana 1990).

* aFaculty of Agriculture, Udayana University, Denpasar 80232; bDepartment of Econometrics and Business
Statistics, Monash University, Clayton, VIC 3800, Australia ; cNSW Agriculture Beef Industry Centre,
dUniversity of New England, Armidale, NSW 2351, Australia.
There are no cattle imported into Bali due to the absolute protection of Bali cattle. However, cattle from Bali are highly demanded outside Bali, especially in Jakarta. DPPB (2000) noted that about 60 per cent of cattle traded in Bali are sent off the island. The island is also known for its extensive tourist sector. Frozen and chilled beef are imported to fulfil the tourist demand. This imported beef competes with the local beef in the tourist sector.

The Bali government has put in place policies for developing this indigenous cattle breed to increase inter-island cattle trade and to improve beef quality to compete with imported beef. A wide range of policies has been implemented to enhance development of Bali cattle including feed supplementation programs, artificial insemination programs and subsidised credit, as well as the national policies mentioned above (Beef NES, Food Security Credit and Food Security Project). However, adding value to livestock through marketing seems to be of little concern. Moreover, the implementation of local autonomy policies and budget self-reliance at the beginning 2001 has encouraged the Bali government to develop local resources such as cattle.

Previous studies of the Bali cattle industry were mainly concerned with the physical productivity of the breed such as feed conversion and carcass weight, and there are very few policy evaluation analyses of the beef sector. Ambarawati et al. (2002) assessed the impact of cattle development schemes on farm performance in Bali, but they did not include any links to the marketing sectors. Knowledge about the distribution of the returns from the development of the cattle industry, including marketing, informs decision making.

The objective of this paper is to develop an economic model of the Bali beef industry to simulate various policies and other exogenous changes. The impact of these changes on various industry groups such as smallholders, processor and consumers, can be estimated in terms of their welfare changes.

**LITERATURE REVIEW**

**The Bali Beef Industry**

The Bali beef industry in this study refers to beef industry on the geographical entity, Bali island (also the Province of Bali). The Bali beef industry involves multiple markets and marketing stages. Demand for beef in Bali comes from two different markets: the wet and higher end markets. The higher end market is also known as the HRI (hotel, restaurant and institutional) market. Demand for fresh beef at the wet market comes from the local population, while frozen and chilled beef are demanded to satisfy the star-rated hotels,
selected supermarkets and catering companies. The quality of beef going to the wet market is not as well graded as the beef supplied to the HRI market. The wet market, which comprises some 80 per cent of the total beef demand in Bali, is fully supplied by Bali beef. On the other hand, the Bali HRI market is currently satisfied by both Bali beef and imported beef. Before the financial crisis in mid 1997, imported beef dominated beef supply to the HRI market and Bali beef accounted for only a small amount of the total beef demand. However, since the financial crisis Bali beef has increasingly been accepted to fulfil demand from the HRI market. Bali beef is now a substitute for imported beef in the HRI market. However, imported beef is not a substitute for Bali beef in the wet market because of preference and quality differences.

**Beef Production for the Wet Market**

Beef processing for the wet market in Bali is undertaken by public abattoirs. Retailers at the wet market cut the carcasses and sell to final consumers. Beef cuts at the wet market are not well-graded as the consumers seem to be indifferent to beef quality. Carcass production from public abattoirs is derived solely from Bali cattle.

In terms of cattle requirements for slaughtering, there are no specific standards of cattle such as weight and age for carcass production at public abattoirs. However, the weight of cattle sold at cattle markets for this market is usually above 300 kg. There is no specification of a production system for cattle in Bali for different purposes such as for wet or HRI markets. Cattle are usually grazed on public fields or maintained under a shed by smallscale farmers. Cattle are sometimes fed with feed supplementation such as rice bran. Heavier cattle are usually selected for the higher end market and for the inter-island trade owing to better quality.

**Beef Production for the HRI Market**

Bali beef production for the HRI market is a different process from the wet market production in terms of cattle selection, processing and marketing phases. Bali beef for the HRI market comes from carcass production from private slaughtering houses. The carcasses produced from private abattoirs are of higher quality to meet retailers’ demand. Certain criteria are usually used for carcass production such as carcass weight and its composition (percentage muscle, bone and fatty tissue). Retailers and packers at the HRI market cut and
trim the carcasses and sell to the consumers. Beef cuts at the HRI market are graded to meet consumers’ requirements.

Cattle are selected at the market by private abattoir operators to obtain higher quality carcasses. This selection is mainly based on physical appearance and cattle weight. The average cattle weight for the HRI market is 375 kg. Some private slaughtering houses have their own cattle contracts with farmers so they can control their cattle weight and quality. While carcasses produced from private abattoirs are mainly directed to the HRI market, by-products and off-cuts of these carcasses are sold to the wet market. It is estimated that 20 per cent of total carcass production from private abattoirs are sent to the wet market. Hence, carcass production from private abattoirs has a multi-output production function. The main difference between private abattoirs and the public abattoirs is in the processing facilities. Private abattoir operations are more mechanised than public slaughtering houses to meet certain grading criteria.

Bali beef competes with imported beef at the HRI market. Hence, the link between the Bali beef and imported beef at the HRI market should be considered in developing the conceptual model. Also, the inter-island cattle trade to the rest of Indonesia market (ROI) should be included in a conceptual model of the Bali cattle market.

Although Bali cattle are sold to different markets, there are no specific cattle producers for each market. All cattle traded come from the same smallholder producers without any product specification. Cattle are valued based on their liveweights. The higher the cattle weight the better the price is.

This review of the Bali beef industry will assist the development of a conceptual model of the industry. A disaggregated model along both horizontal and vertical lines is required to capture policy changes occurring in the different markets.

**A Conceptual Model of the Bali Beef Industry**

The Bali beef industry is disaggregated into a horizontal and vertical structure to examine the benefits of government policies and research that occurs in various industry sectors and markets, as well as the distribution of benefits among different industry groups. Horizontally, the market is segmented based on the type of beef demanded: wet and HRI markets. Vertically, beef production and marketing are disaggregated into cattle supply, processing, marketing and consumption. This segmentation enables separate analyses of
various policies at different stages of marketing. Inputs other than the cattle input are treated as a general ‘marketing input’ in all sectors.

The demand for imported beef at the HRI market is included in this segmentation. The quantity of imported beef is treated as an endogenous variable in the model, but the price of imported beef is treated as an exogenous variable. As Indonesia is not a major player in beef imports in the world market, it is considered that the supply of imported beef is perfectly elastic. On the other hand, the demand for imported beef is assumed to be downward sloping.

The model also includes the rest of Indonesia (ROI) market in order to capture the impacts of inter-regional trade on Bali cattle production. It is believed that any changes in beef demand outside Bali will affect cattle production in Bali. The Bali geographical market and the ROI market are linked through quantity of cattle traded and the cattle price. Any policy changes occurring in the ROI market is treated as an exogenous shifter to the Bali cattle production.¹

Based on the industry structure reviewed above, the model of the Bali beef industry is specified in Appendix 1. As shown in the figure, there are four production functions, represented by rectangles on the diagram. From each production function creates the demand and supply for a product represented by the ovals on the diagram. In each supply or demand schedule an exogenous shift may occur. The inclusion of the exogenous shifters in this model enables separate analyses of various policies at the farm level, processing stage and retail marketing. There are 13 factor or product markets involving 24 quantity and price variables. There are also two aggregated input and output index variables for the processing sector at private abattoirs. This gives 26 endogenous variables for the 26 equations and identities in the system. The definitions of all variables and parameters in the model are presented in Appendix 2. The structural model of the Bali beef industry which describes the links among the variables is presented in the Appendix 3.

**METHODOLOGY**

**The Model**

This research is based on a synthetic model, often referred to as an Equilibrium Displacement Model (EDM). EDM has been frequently used in agricultural price and policy

---

¹ A larger version of the model is also available where the ROI sector is fully endogenous. However, given the relative sizes of the beef markets in the two geographic sectors, little extra information is provided by using this version.
analysis. The EDM involves the application of comparative static analysis to general function models. The main strength is that it allows quantitative assessments to be made of the impacts on endogenous variables of small changes in exogenous variables in situations where there are no resources available to engage in econometric modelling (Piggott 1992). In the EDM approach, the market is disturbed by a change in the value of exogenous variable and the impacts of the disturbance are approximated by functions which are linear in elasticities.

The exogenous shifters examined are improved productivity, promotion and policy changes in beef marketing arrangements. The relationships among changes in all endogenous variables due to exogenous shifters can be derived by totally differentiating the system of equations at the initial equilibrium points. The consequent changes in producer and consumer surplus reflecting welfare changes at the various stages of marketing can then be estimated.

The impacts of a 1 per cent reduction in per unit cost resulting from productivity advances in cattle production supported by the Bali government intervention program is simulated. However, the cost of achieving the 1 per cent change is not addressed in this study. Changes in prices and quantities in all markets due to this exogenous shift are estimated, and consequent changes in producer and consumer surplus in the relevant markets are presented. Finally, alternative scenarios of exogenous shifters resulting from increased efficiencies and policy changes in different industry sectors are simulated. Comparisons of welfare changes among different scenarios are conducted.

**Data Requirements**

Operation of the EDM requires three different sets of information. Firstly, base price and quantity values are needed for all endogenous variables to portray the base equilibrium status of the system. Secondly, various elasticity values are needed. Finally, values all exogenous shifters are needed to quantify the impact of policy changes at different levels of marketing.

The availability of data is very limited. The Central Bureau of Statistics of Indonesia (CBSI) and the Directorate General of Livestock Services (DGLS) provide annual data on beef production for all provinces in Indonesia, measured in kilotons carcass weight. However, there is no published information on final beef products such as the quantity of beef entering the wet and HRI markets respectively. Information on the quantities of carcass produced from public and private abattoirs is also lacking. Hence, assumptions are made on
the proportion of carcasses produced at different abattoirs and beef produced for the wet and HRI markets based on the information provided by DGLS staff, Bali Regional Livestock Services staff and other industry agencies. Considerable effort has been made in this study to assemble a set of equilibrium quantities and prices at different stages. These include a survey of public and private abattoirs, hotels and restaurants in Bali to obtain the required information. A combination of published information and the survey information has been used to estimate the data required at the different levels and market segments.

Price and quantity values used in this study are based on the year 2000 assuming that the beef market situation in Indonesia had returned to normal after the 1997 financial crisis. There was a sharp increase in imported beef into Indonesia, from 10.55 kt in 1999 to 26.96 kt in 2000. Beef imported into the Bali HRI market increased from 165 tonnes in 1999 to 300 tonnes in 2000. This is a good indication that the economy is gradually recovering from the financial crisis.

Market parameters required in the model include the elasticity values of various beef demand and input supplies, input substitution and product transformation. Parameter values are selected on the basis of economic theory, past studies of the beef industry and intuition.

There are eight exogenous shift variables in this study allowing different scenarios resulting from different policies and research in the Bali beef industry to be examined. Improved productivity of cattle production and increased efficiencies in processing and marketing sectors are modelled as reducing cost of production in the relevant sectors. This can be seen as an outward or downward supply shift. Beef promotion in the Bali market and policy changes in the ROI market are modelled as an outward shift in demand. Equal 1 per cent vertical shifts in the relevant supply and demand curves are assumed for all eight main scenarios. This allows for the simulation of the impacts of 1 per cent cost reductions in different production, processing and marketing sectors as well as 1 per cent increase in consumer's willingness to pay at the final stage of the products. These are explained in Appendix 4.

RESULT AND DISCUSSION

Returns from Alternative Cattle Development Policies

Having specified initial prices and quantities and market elasticities, the resulting percentage changes in all prices and quantities are calculated by simulating the model described in the Appendix 3 for each of the scenarios described in Appendix 4. Using the
changes in prices and quantities, the changes in economic surplus for the various groups are calculated. The results of the total welfare changes and their distribution among industry groups such as cattle producers, processors, retailers and consumers for each of the eight scenarios are presented in Table 1.

Some prerequisite of the results should be noticed before any comparison is undertaken. This study relates to equal 1 per cent exogenous shifts in the relevant supply and demand curves but the costs required to bring about 1 per cent shift is not addressed here. Therefore, the monetary benefits from alternative scenarios in Table 1 are only comparable under the assumption of equal investment efficiency, in the sense that the investment costs of the 1 per cent shifts in all sectors are the same. This indeed is unlikely to be true in reality. Issues regarding the efficiency of investments have been discussed by a number of authors include Lemieux and Wohlgenant (1989), Scobie et al. (1991) and Zhao (2000). Zhao (2000) also pointed out that despite the same amount of investments at different points of the industry may cause demand and supply shifts of different magnitudes, and despite the actual
returns in monetary terms are dependent on the magnitudes of the initial shifts, the
distribution of the total benefits among industry groups is independent of the size of the
initial shift. Accordingly, it is always worthwhile to compare shares of benefits among
alternative investment scenarios without knowledge of the efficiency of research investment.

The results indicate that the size of total economic surplus changes is determined
largely by the total value of the sector where the exogenous shift occurs. As can be seen
from Table 1, for the same 1 per cent exogenous shift in the relevant market, improved
productivity of Bali cattle production resulting from government intervention (Scenario 1)
has the largest total benefits (Rp 3.02 billion, about A$ 0.60 million). This is about 1 per cent
of the total value of Rp 301.83 billion at the farm gate. Meanwhile, policy changes from the
ROI market (Scenario 8) amounts to Rp 1.71 billion (A$ 0.34 million). The total returns from
the beef promotion scenario in the wet market is Rp 1.297 billion (A$ 0.26 million) but those
are much smaller returns for beef promotion in the HRI market (Rp 0.463 billion). The total
benefits from improved efficiencies in the processing and marketing sectors (Scenario 2 – 5) are very small, ranging from Rp 0.032 billion to Rp 0.20 billion. These small returns are due to the small value added to the beef products in those sectors and the highly elastic nature of the supply of other inputs.

In terms of the distribution of returns among various industry groups, Bali cattle producers receive substantial benefits (43 per cent to 70.17 per cent of total returns) from any cost reduction or improved efficiency scenarios. This is because cattle production has the highest value within the industry group. On the other hand, Bali beef consumers in both the wet and HRI markets gain much less surplus than cattle farmers. Moreover, the ROI consumers only receive gains from the cost reduction in Bali cattle production but the benefits are much bigger than for beef consumers. The total value of cattle shipped outside Bali is much bigger than the beef value at the final stage in Bali. However, any improved efficiencies at the marketing level in Bali (Scenario 2 –5) result in a welfare loss to the ROI consumers. This is because less cattle are traded to the ROI market. The small portion of welfare gains to the processing and retail sectors are due to the assumption of very elastic supply curve for marketing inputs (with an elasticity of 5). This means that marketing firms can purchase more inputs without paying suppliers substantially higher prices.

The results of these simulations also suggest that the quantity of imported beef entering the HRI market is reduced by 0.08 per cent for a 1 per cent cost reduction in any of the marketing stages. This implies that government policy aimed at reducing beef imports can be met by increasing efficiencies in the relevant sector, such as reducing the cost of Bali cattle production, resulting in more Bali beef entering the HRI market.

These results can be ranked according to various criteria. Here it is ranked according to both absolute returns to farmers and the percentage share of total returns going to farmers (Table 2). Farmers are the focal point because the stated objectives of the cattle development policies are to enhance the livelihoods of the smallholder cattle producers. Scenarios 1 and 8, and to a lesser extent Scenario 6, dominate both rankings. Thus decreasing the cost of producing cattle, generating greater demand from the inter-island market, or inducing consumers in the Bali wet market to pay more for beef, are the three main ways that Bali cattle producers can benefit from industry development.

Another way of looking at these results is to calculate the percentage shifts required in the other market sectors to provide the same return to cattle producers (Rp1.95 billion, about A$ 0.39 million) as greater efficiencies in cattle production (Table 3). Again, Scenarios 6 and
8 require greater shifts than Scenario 1 but of the same broad order of magnitude, while the other Scenarios require shifts between nine and 122 times larger, to provide Rp 1.95 billion to farmers.

CONCLUSION AND POLICY IMPLICATION

Conclusion

The Bali government has put in place policies for developing the Bali cattle breed to increase the inter-island live cattle trade and to improve Bali beef quality to compete with imported beef in the tourist sector in Bali. Information on the benefits from development of the cattle industry is limited and therefore evaluation of the policies is required to guide future policy development. In this paper, an economic model of the Bali beef industry was developed to simulate various policies and exogenous changes. The impacts of these changes on various industry groups were examined in terms of their welfare changes.
For a 1 per cent exogenous shift in the relevant market, improved productivity of Bali cattle production has the largest total benefits (Rp 3.02 billion, about A$ 0.6 million). Increased demand from the ROI market amounts to Rp 1.71 billion (A$ 0.34 million), and from the wet market is Rp 1.297 billion (A$ 0.26 million). The total benefits from improved efficiencies in the processing and marketing sectors are very small, ranging from Rp 0.032 billion to Rp 0.20 billion. In terms of the distribution of returns among various industry groups, Bali cattle producers receive substantial benefits (43 to 70 per cent of total returns) from any cost reduction or improved efficiency scenarios. This is because cattle production has the largest value within the industry sectors. Bali beef consumers in both the wet and HRI markets gain much less surplus than cattle farmers.

Policy Implication

The model seems appropriate for examining different types of R&D and policy scenarios to those described above. For example, estimates of the cost savings from particular types of policies (see Ambarawati et al. 2002) can be used as input rather than hypothetical 1 per cent shifts. However more research is needed in several areas. In particular, since the data are quite scarce and there is much uncertainty about some of the assumptions made, formal sensitivity analyses are required to ensure that the generated results are not highly dependent on particular assumed values.

Appendix 3  Model Specification of the Bali Beef Industry

Demand for Bali beef at Bali wet market:
(1) \[ Y_{14} = a(Y_1, N_{Y_1}) \]

Supply function of Bali beef at Bali wet market (market clearing condition):
(2) \[ Y_{14} = c(Y_{16}, Y_{19}, Y_{47}) \]

This equation expresses the long-run equilibrium condition that output price equals average per unit cost c(.).

When the production function shows constant return to scale, the industry total cost function can be written as:
\[ C_{Y_1} = Y_1c_{Y_1}(Y_{16}, Y_{19}, Y_{47}) \]

\( C_{Y_1} \) is the total cost of producing output \( Y_1 \) and \( cy_1(.) \) is the unit cost function. The output-constrained input demand functions can be derived by applying Shephard’s lemma. Imposing zero homogeneity in input prices allows the cross-price elasticity terms to be expressed in terms of cost shares and the elasticity of substitution between inputs via the Allen decomposition of output-constrained input demand elasticities.

The output-constrained input demand of Bali beef production at Bali wet market:
(3) \[ Y_3 = Y_1c'_{Y_1,Y_3}(Y_{16}, Y_{19}, Y_{47}) \] demand for carcass from public abattoirs
(4) \[ Y_9 = Y_1c'_{Y_1,Y_9}(Y_{16}, Y_{19}, Y_{47}) \] demand for marketing input 1
(5) \[ Y_{46} = Y_1c'_{Y_1,Y_{46}}(Y_{16}, Y_{19}, Y_{47}) \] demand for carcass from private abattoirs

\( c'_{Y_1,Y_n}(Y_{16}, Y_{19}, Y_{47}) \) (n=3, 9, 46) are partial derivatives of the unit cost functions \( cy_1(Y_{16}, Y_{19}, Y_{47}) \).

Marketing input supply to Bali beef production at Bali wet market:
(6) \[ Y_{19} = b(Y_9, T_{Y_9}) \] supply of marketing input 1

Bali public abattoir carcass production function
(7) \[ Y_{16} = d(Y_{18}, Y_{21}) \]

This equation expresses the long-run equilibrium condition that output price equals average per unit cost d(.).

Total cost function at public abattoirs can be written as:
\[ C_{Y_3} = Y_3c_{Y_3}(Y_{18}, Y_{21}) \]

\( C_{Y_3} \) is the total cost of producing output \( Y_3 \) and \( cy_3(.) \) is the unit cost function. The output-constrained input demand functions can be derived by applying Shephard’s lemma. Imposing zero homogeneity in input prices allows the cross-price elasticity terms to be
expressed in terms of cost shares and the elasticity of substitution between inputs via the Allen decomposition of output-constrained input demand elasticities.

Output-constrained input demand of carcass production at Bali public abattoirs

\( Y_6 = Y_3 \cdot c'_{Y3,Y6}(Y_{18}, Y_{21}) \) demand for Bali cattle at public abattoirs

\( Y_{11} = Y_3 \cdot c'_{Y3,Y11}(Y_{18}, Y_{21}) \) demand for marketing input 3

\( c'_{Y3,Y6}(Y_{18}, Y_{21}) \) (n=6, 11) are partial derivatives of the unit cost functions \( c_{Y3}(Y_{18}, Y_{21}) \).

Marketing input supply to carcass production at Bali public abattoirs

\( Y_{21} = c(Y_{11}, T_{y11}) \) supply of marketing input 3

Demand for Bali beef at Bali HRI market

\( Y_{15} = f(Y_2, N_{y2}, X_1) \)

Supply function of Bali beef at Bali HRI market

\( Y_{15} = g(Y_{17}, Y_{20}) \)

Output-constrained input demand of Bali beef production at Bali HRI market

\( Y_4 = Y_2 \cdot c'_{Y2,Y4}(Y_{17}, Y_{20}) \) demand for carcass at private abattoirs

\( Y_{10} = Y_2 \cdot c'_{Y2,Y10}(Y_{17}, Y_{20}) \) demand for marketing input 2

Marketing input supply to Bali beef production at Bali HRI market

\( Y_{20} = h(Y_{10}, T_{y10}) \) supply of marketing input 2

Bali private abattoir carcass production function

\( Z_{BO}(Y_4, Y_{46}) = Z_{BI}(Y_7, Y_{12}) \) quantity equilibrium of carcass production

Equation (16) is the product transformation function for the processing sector that equalises the aggregated output index \( Z_{BO} \) with the aggregated input index \( Z_{BI} \).

\( r_{ZBO}(Y_{17}, Y_{47}) = c_{ZBI}(Y_{18}, Y_{22}) \) value equilibrium

Equation (17) is an equilibrium condition stating that the unit revenue \( r_{ZBO} \) earned per unit of aggregated input \( Z_{BI} \) equals the unit cost \( c_{ZBI} \) of producing a unit of aggregated output \( Z_{BO} \).

Input-constrained output supply of carcass at Bali private abattoirs

\( Y_4 = Z_{BI} \cdot r'_{ZBI}, Y_{44}(Y_{17}, Y_{47}) \)

\( Y_{46} = Z_{BI} \cdot r'_{ZBI}, Y_{46}(Y_{17}, Y_{47}) \)

Output-constrained input demand of carcass production at Bali private abattoirs

\( Y_7 = Z_{BO} \cdot c'_{ZBO,Y7}(Y_{18}, Y_{22}) \)

\( Y_{12} = Z_{BO} \cdot c'_{ZBO,Y12}(Y_{18}, Y_{22}) \)

Marketing input supply to carcass production at private abattoirs in Bali

\( Y_{22} = i(Y_{12}, T_{y12}) \) supply of marketing input 4
Demand for imported beef in Bali

(23) \[ Y_{13} = j(X_1, N_{x1}, Y_{15}) \]

Inter-island Bali cattle demand

(24) \[ Y_8 = k(Y_{18}, N_{y8}) \]

Bali cattle supply to Bali and ROI markets

(25) \[ Y_{18} = q(Y_5, T_{y5}) \]

Market clearance of Bali cattle

(26) \[ Y_5 = Y_6 + Y_7 + Y_8 \]

Appendix 4 Various Scenarios for Exogenous Shift Variables

Scenario 1: Bali cattle production research.
\[ t_{y5} = -0.01, \text{ the rest of } t(.) = 0 \text{ and } n(.) = 0. \]
Cost reduction in Bali cattle production resulting from improved productivity encouraged by Bali government in cattle development.

Scenario 2: Processing research at public abattoirs Bali market
\[ t_{y11} = -0.01, \text{ the rest of } t(.) = 0 \text{ and } n(.) = 0. \]
Reduction in processing cost in public abattoirs in Bali resulting from improved management and efficiency.

Scenario 3: Processing research at private abattoirs Bali market.
\[ t_{y12} = -0.01, \text{ the rest of } t(.) = 0 \text{ and } n(.) = 0. \]
Reduction in processing cost in private abattoirs in Bali resulting from new technologies and improved management strategies.

Scenario 4: Marketing research at wet market.
\[ t_{y9} = -0.01, \text{ the rest of } t(.) = 0 \text{ and } n(.) = 0. \]
Cost reduction in the Bali wet market resulting from new technologies and improved management.

Scenario 5: Marketing research HRI market.
\[ t_{y10} = -0.01, \text{ the rest of } t(.) = 0 \text{ and } n(.) = 0. \]
Cost reduction in the Bali HRI market due to improved technologies and management.

Scenario 6: Bali beef promotion at wet market.
\[ n_{y1} = 0.01, \text{ the rest of } t(.) = 0 \text{ and } n(.) = 0. \]
Increase in the willingness to pay by beef consumers at the wet market resulting from beef promotion.

Scenario 7: Bali beef promotion at HRI market.
\[ n_{y2} = 0.01, \text{ the rest of } t(.) = 0 \text{ and } n(.) = 0. \]
Increase in the willingness to pay by beef consumers at the HRI market resulting from Bali beef promotion.
Scenario 8: Policy changes at ROI market.

\( n_{38} = 0.01, \) the rest of \( t_{13} = 0 \) and \( n_{13} = 0. \)

Increase in the willingness to pay by beef consumers at the ROI market resulting from policy changes as guaranteed quality.
